

# Eaze Referral Program

Product brief · the idea, the flow, and how it's rewarded

Eaze's referral program turns any user into a recruiter without ever leaving the app. A banner inside Eaze opens a lightweight webapp where a user names a specific friend's phone number; when that friend signs up with the same number and later makes their first recharge, both people are credited 50 coins — automatically, with no manual codes to share, no deep-link SDK to maintain, and zero changes required to Eaze's own signup screen.

## How it works

| Referrer                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Referred friend                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ol style="list-style-type: none"><li>1. Taps the “Refer a friend” banner inside the Eaze app.</li><li>2. Webapp opens already signed in — identity is handed off in the banner link itself.</li><li>3. Copies a ready-made invite message and shares it anywhere.</li><li>4. Types their friend's phone number into the form — this step is what actually creates the referral.</li><li>5. Gets notified as coins land: once at signup, once at recharge.</li></ol> | <ol style="list-style-type: none"><li>1. Receives the message, taps the link, installs Eaze.</li><li>2. Signs up with their phone number — no code to enter, nothing extra to do.</li><li>3. If it matches the number their friend named, 50 coins land immediately.</li><li>4. Recharges whenever they naturally would — that single action pays their referrer.</li></ol> |

## Reward mechanics

|                 |                                                                                     |
|-----------------|-------------------------------------------------------------------------------------|
| Referred friend | 50 coins the instant they sign up with a phone number their referrer already named. |
| Referrer        | 50 coins the instant that friend's first-ever recharge succeeds.                    |
| Every credit    | Idempotent — a retried request or webhook can never pay the same reward twice.      |

## Why attribution is phone-only, not a code

Most referral programs lean on a shareable code or a deep-link that has to survive an app-store install — notoriously unreliable, especially on iOS. Eaze's program inverts that: the referrer names their friend's number **up front**, before the friend has even installed the app. That's a stronger signal than a code anyone could copy and paste with no real tie to the referrer, and because it needs no code field anywhere in the signup flow, the real Eaze app required zero changes to support it.

## What it looks like

The webapp a user lands on after tapping the banner — real screenshots, not mockups.

Referrer's screen — invite message and the phone number form

"Copy message" — one tap, ready to paste into WhatsApp

"Save numbers" — the referral relationship is created the moment this succeeds

No valid link, no access — refuses to work outside a real banner tap

**Under the hood:** Python/FastAPI + PostgreSQL, containerized and Kubernetes-ready (verified against a live 3-pod deployment with a one-shot migration Job), every login, phone submission, and message-copy event logged in IST for reporting.
